

Questionnaire: Live VR Interaction Label

Participant Response Sheet – VR Developers / Expert

Participant facing copy. Use the scale shown unless the question has its own answer choices.

In this questionnaire, the tool refers to the live label shown during gameplay. The post gameplay frequency report refers to the frequency of the detected issues captured during the entire gameplay session.

Section 1 - VR Interaction Usability

1. The live label was clear during gameplay. I could tell what it referred to and what status it was showing.

Choose one: 4 Agree

2. The live label helped me understand what the VR application expected me to do.

Choose one: 4 Agree

3. The live label helped me notice when an interaction needed attention.

Choose one: 3 Neutral / not sure

4. The live label helped me tell whether my action matched the visual cues and VR app response.

Choose one: 3 Neutral / not sure

5. The live label helped me adjust or recover when something went wrong.

Choose one: 5 Strongly agree

6. The live label would help me reproduce or explain an interaction issue later so that the issue can be tested again more consistently.

Choose one: 4 Agree

Section 2 - Developer Feedback

7. The post gameplay frequency report accurately reflected how often issues occurred during my session.

Choose one: 4 Agree

8. The post gameplay frequency report would help rank or prioritize issues based on how often they occurred, how long they persisted, or how much of the session they affected.

Choose one: 2 Disagree

9. The live label would provide enough information to create or update a bug report.

Choose one: 3 Neutral / not sure

10. The live label could support automated or semi-automated review by flagging issues or moments that need human inspection.

Choose one: 4 Agree

11. Overall, the tool was accurate enough to be useful for VR testing.

Choose one: 4 Agree

Section 3 – Safety, Body Tracking and Movement Feedback

For this section: body location means where spatially the user/avatar is positioned in the virtual scene; body orientation means which way the user/avatar is facing; posture means the body pose or stance; movement symmetry means whether left and right movements appear balanced; floor/ground plane means the expected virtual floor/ground height reference.

12. The live label could help evaluate whether an issue is related to interaction behavior, body tracking, or user safety.

Choose one: 4 Agree

13. It would be useful to know whether missing, unstable, or poorly tracked body parts affected the label.

Choose one: 4 Agree

14. It would be useful to know whether the user's body location or occupied space in the scene affected the label.

Choose one: 4 Agree

15. It would be useful to know whether the user's body orientation or posture affected the label.

Choose one: 4 Agree

16. It would be useful to know whether the user's relationship to the floor or ground plane affected the label.

Choose one: 4 Agree

17. The live label would help give users feedback before unsafe or excessive movement is repeated.

Choose one: 3 Neutral / not sure

Section 4 - Open-Ended Review

18. VR Application tested:

All

19. What interaction elements were specific to this VR app?

picking, kicking, leaning, dogging, hand movements

20. What did you notice that stayed the same across VR apps, and what changed between VR apps?

In most games the position is important and it was the primary reason for failure. the way of interaction between games were different, some were kicking, some grabbing and some leaning. The way I moved my body or specifically hands and head would more frequently throw the alarms.

21. How did a failure case appear in this game? For example, was there a missing action, delayed response, incorrect object selection, unsafe movement, or unclear feedback?

Mostly my positioning in front of the camera, the way I moved my head and hands and lastly if I made an interaction that is not normal in the game.

22. Describe one moment where the live label helped you understand, recover from, or review an interaction.

In the popping bollons game, when my position was not accurately captured by the camera, the label helped me to adjust my position for a more accurate gameplay.

23. What information should be logged with each label to make it more actionable for debugging, safety, body tracking, or interaction review?

It would be more effective if we could tell what exactly caused the error. For instance, body positioning, or incorrect movement in a game like turning the head.
